Artificial Intelligence

Informed search

Today: Informed search

- Providing hints for the search using a heuristic
- Greedy best-first search
- A* search
- Admissible heuristics
- Consistent heuristics
- Search contours
- Memory-bounded search: beam search
- Heuristics for the 8-puzzle

Uninformed search

- Search strategy that uses no problem-specific knowledge

Informing the search using heuristics

Informing the search using heuristics

Informing the search using heuristics

- Manhattan distance

Informing the search using heuristics

- Straight-line distance

Providing hints for search using heuristics

- **Choosing the Fastest Checkout Line**
- **Question:** You walk into a supermarket and see multiple checkout lines. You want to check out quickly. Would you:
 - Count every item in each customer's cart to calculate exactly which line will move fastest?
 - Estimate which line might be faster by looking at the number of people, cart sizes, and how fast the cashier is working?
- **What factors help you make a quick but effective decision?**

Providing hints for search using heuristics

- **Choosing the Fastest Checkout Line**
- **Question:** You walk into a supermarket and see multiple checkout lines. You want to check out quickly. Would you:
 - Count every item in each customer's cart to calculate exactly which line will move fastest?
 - Estimate which line might be faster by looking at the number of people, cart sizes, and how fast the cashier is working?
- **What factors help you make a quick but effective decision?**
- **Expected Heuristic:** Choose the shortest line with the fewest items and the fastest-moving cashier.

Providing hints for search using heuristics

- **Guessing a Word in a Crossword Puzzle**
- **Question:** You are solving a crossword puzzle, and a missing word looks like this: "S_N_". Would you:
 - Go through the dictionary, checking every possible word
 - Think of common words that fit the pattern, like "SAND" or "SONG"?
- **How does your brain quickly filter out unlikely words?**

Providing hints for search using heuristics

- **Guessing a Word in a Crossword Puzzle**
- **Question:** You are solving a crossword puzzle, and a missing word looks like this: "S_N_". Would you:
 - Go through the dictionary, checking every possible word
 - Think of common words that fit the pattern, like "SAND" or "SONG"?
- **How does your brain quickly filter out unlikely words?**
- **Expected Heuristic:** Use letter patterns and context to prioritize likely words.

Informed search

- Search strategy that uses problem-specific knowledge (heuristics) to find solutions more efficiently

Greedy best-first search

- Let $g(n)$ represent a simple function that returns a path cost for a node n
- Dijkstra's algorithm uses the evaluation function $f(n) = g(n)$ in the priority queue for the search frontier to choose the node to expand.
 - UCS is Dijkstra's algorithm for a single goal
- Potential problem: it may be cheap to get to the candidate node's state but expensive to get from that state to the goal!
- Idea: estimate the cost of the cheapest path from the candidate node's state to a goal state and use this to modify the value returned by $f(n)$
- Greedy best-first search algorithm expands the node that is closest to the goal state, as estimated by a heuristic function $h(n)$
- It ignores how costly it was to get to n and *greedily* expands the node that is gauged to be closest to a goal according to $h(n)$
- Greedy best-first search: $f(n) = h(n)$

Greedy best-first search

```
1  Function GBFS(problem, h)
2      frontier = PQ{f=h, Node(problem.initial_state)}
3      while (true)
4          if (frontier.empty) return fail
5          node = pop_min_f(frontier)
6          if (node.state is goal) return solution
7          for c in Expand(node, problem)
8              frontier.add(c)
```

A heuristic for route finding (in Romania)

- Assuming Bucharest is the goal state, the following table gives values for a suitable heuristic function $h(n)$
 - The values are the straight-line distances from the relevant town (“state”) to the goal state, i.e., we use the **straight-line distance**

Arad	366	Mehadia	241
Bucharest	0	Neamt	234
Craiova	160	Oradea	380
Drobeta	242	Pitesti	100
Eforie	161	Rimnicu Vilcea	193
Fagaras	176	Sibiu	253
Giurgiu	77	Timisoara	329
Hirsova	151	Urziceni	80
Iasi	226	Vaslui	199
Lugoj	244	Zerind	374

Route finding from Arad to Bucharest

Greedy best-first search

- Starting with the town Arad as the initial state, greedy best-first search will expand the search tree as shown on the next slide
- It finds a solution (guaranteed for finite search spaces), but this solution is not necessarily optimal
- In this example, the route found, via Sibiu and Fagaras, is 33 units longer than the optimum one

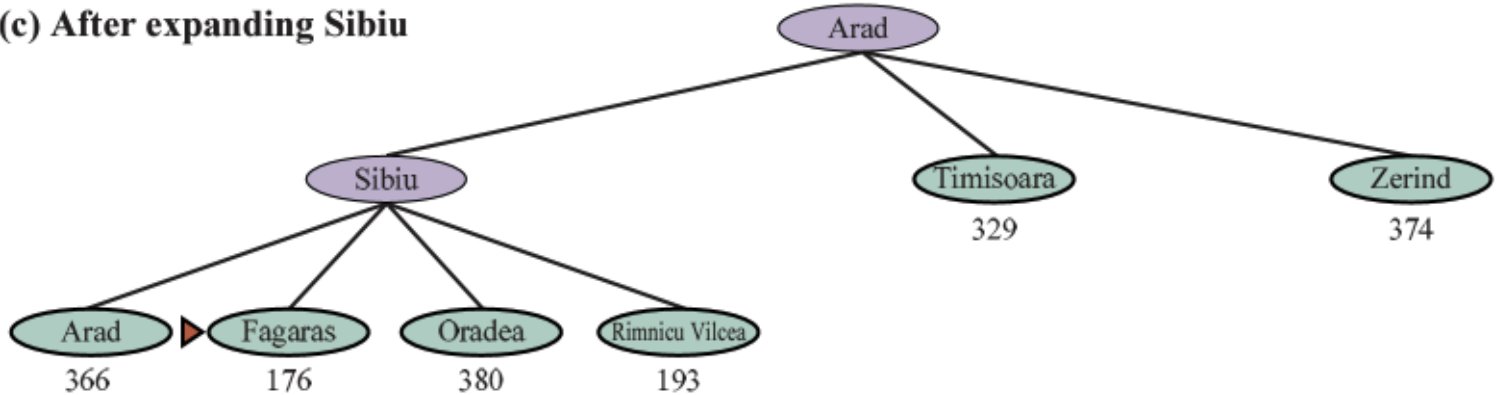

(a) The initial state

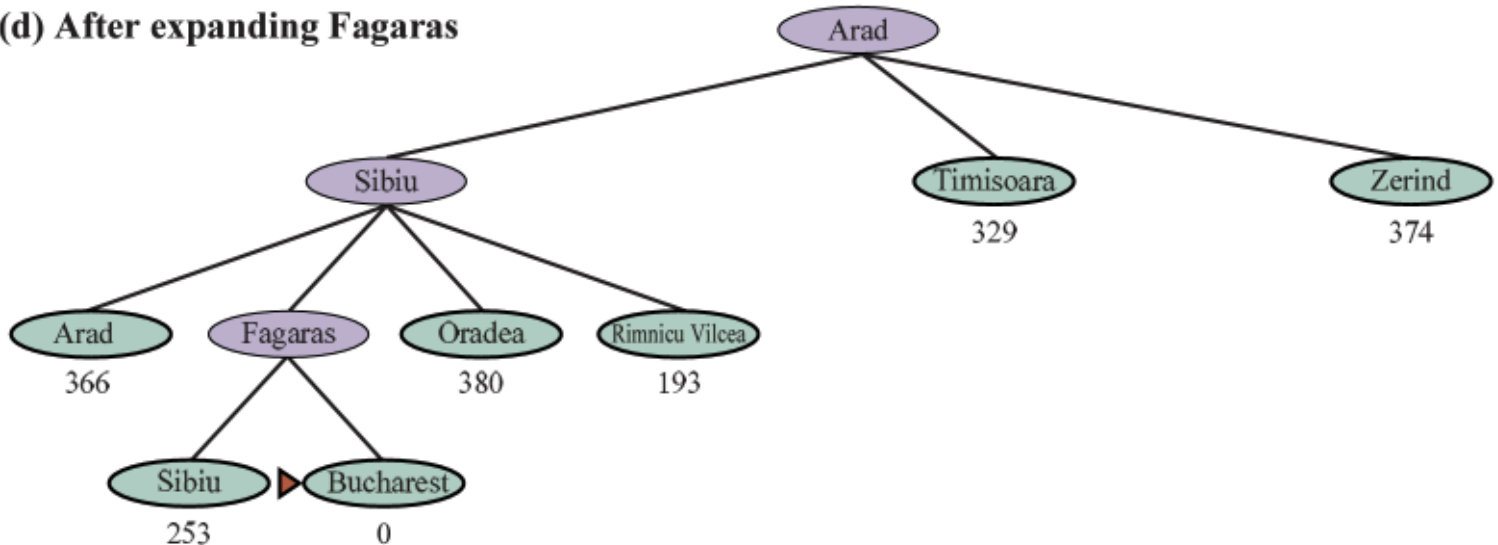

(b) After expanding Arad

(c) After expanding Sibiu

(d) After expanding Fagaras

A* search

- Search algorithm that expands node with lowest value of $g(n) + h(n)$
 - $g(n)$ = cost to reach node
 - $h(n)$ = estimated cost to goal state
- Given an estimate to a goal state $h(n)$ we can use $f(n) = g(n) + h(n)$ in the best-first search algorithm to get a **heuristic** (i.e., **informed**) **search** known as **A* search**
- A* search: $f(n) = g(n) + h(n)$

Greedy best-first search

```
1  Function GBFS(problem, h)
2      frontier = PQ{f=h, Node(problem.initial_state)}
3      while (true)
4          if (frontier.empty) return fail
5          node = pop_min_f(frontier)
6          if (node.state is goal) return solution
7          for c in Expand(node, problem)
8              frontier.add(c)
```

A* search

```
1 Function AStar(problem, h)
2   frontier = PQ{f=g+h, Node(problem.initial_state)}
3   while (true)
4     if (frontier.empty) return fail
5     node = pop_min_f(frontier)
6     if (node.state is goal) return solution
7     for c in Expand(node, problem)
8       frontier.add(c)
```

A* search: using $f(n) = g(n) + h(n)$

(a) The initial state

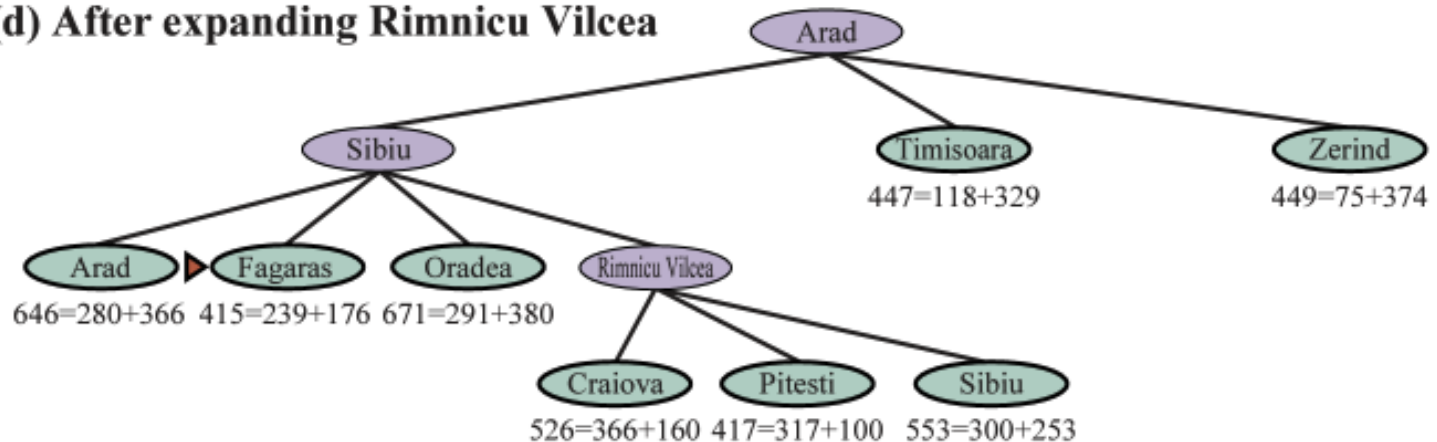

(b) After expanding Arad

(c) After expanding Sibiu

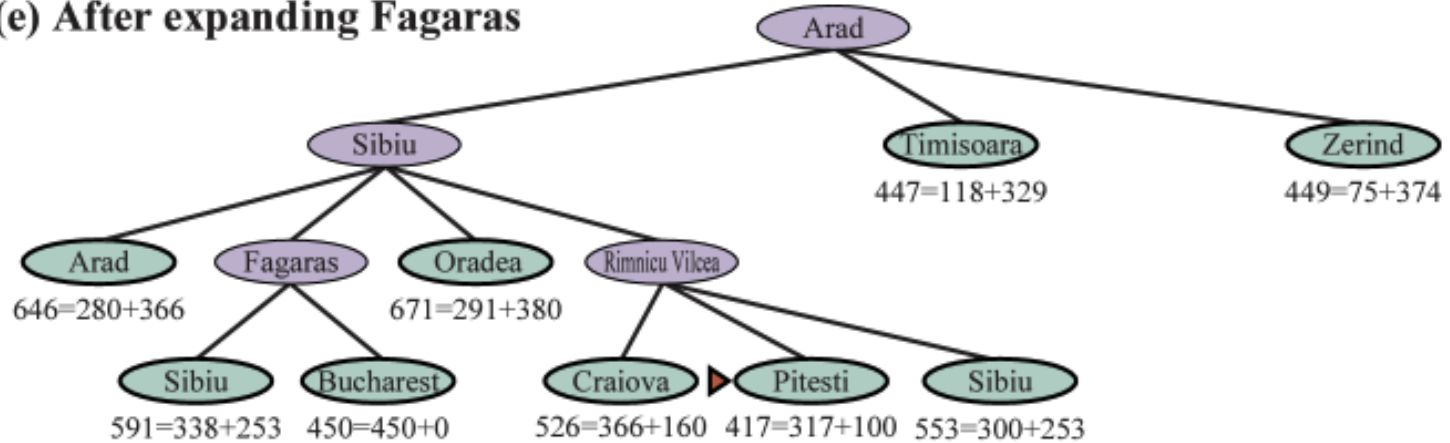

(d) After expanding Rimnicu Vilcea

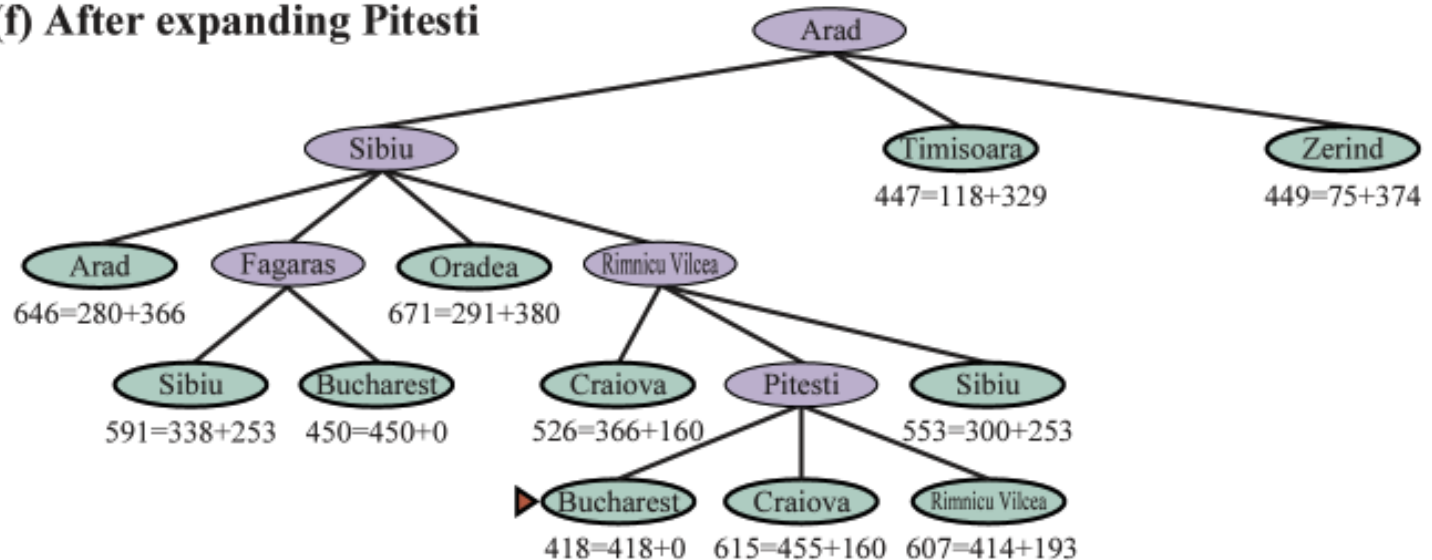

A* search continued

(e) After expanding Fagaras

(f) After expanding Pitesti

Uniform-cost search updated

```
1  Function UCS(problem)
2      reached = {}
3      frontier = PQ{f=g, Node(problem.initial_state)}
4      while (true)
5          if (frontier.empty) return fail
6          node = pop_min_f(frontier)
7          if (node.state is goal) return solution
8          if (node.state in reached) continue
9          reached.add(node.state)
10         for c in Expand(node, problem)
11             frontier.add(c)
```

Greedy best-first search updated

```
1  Function GBFS-Updated(problem)
2      reached = {}
3      frontier = PQ{f=h, Node(problem.initial_state)}
4      while (true)
5          if (frontier.empty) return fail
6          node = pop_min_f(frontier)
7          if (node.state is goal) return solution
8          if (node.state in reached) continue
9          reached.add(node.state)
10         for c in Expand(node, problem)
11             frontier.add(c)
```

A* search updated

```
1  Function UCS(problem)
2      reached = {}
3      frontier = PQ{f=g+h, Node(problem.initial_state)}
4      while (true)
5          if (frontier.empty) return fail
6          node = pop_min_f(frontier)
7          if (node.state is goal) return solution
8          if (node.state in reached) continue
9          reached.add(node.state)
10         for c in Expand(node, problem)
11             frontier.add(c)
```

Admissible heuristics

- We want the estimate of the cost provided by $h(n)$ to be as accurate as possible (while being cheap to compute!)
 - Ideally, the heuristic function would give us the true cost of the shortest path from the candidate node's state to a goal state
- Is A* search guaranteed to give use the lowest cost path?
- Yes, assuming the heuristic function is optimistic and *never overestimates* the true cost of getting to a goal state
 - Optimality can be shown using a proof by contradiction
- The straight-line distance is a suitable optimistic heuristic in the route-finding problem: it will never be greater than the actual distance
 - $0 \leq h(n) \leq h^*(n)$; where $h^*(n)$ is the true cost to the nearest goal
- This kind of optimistic heuristic is called **admissible**
- We want admissible heuristics whose estimates are as close as possible to the true cost of the path!

Consistent heuristics

- For search efficiency, it would be nice to be able to guarantee the following condition during A* search:
 - The first time we reach a state (i.e., create a node for a state in the search tree), this will be on an optimal path to the goal
 - Then, the state will only ever occur once in the frontier, and we will never update the best node in the dictionary of reached states
- This can be achieved by using a heuristic that is not just **admissible** but also **consistent**:

$$h(n) \leq c(n, a, n') + h(n')$$

where $c(n, a, n')$ is the cost of taking action a

A* search

- Optimal if
 - $h(n)$ is admissible (never overestimates the true cost), and
 - $h(n)$ is consistent (for every node n and successor n' with step cost c , $h(n) \leq c(n, a, n') + h(n')$)

Search contours: UCS vs A*

- Uniform-cost expands equally in all “directions”

- A* expands mainly toward the goal, but does hedge its bets to ensure optimality

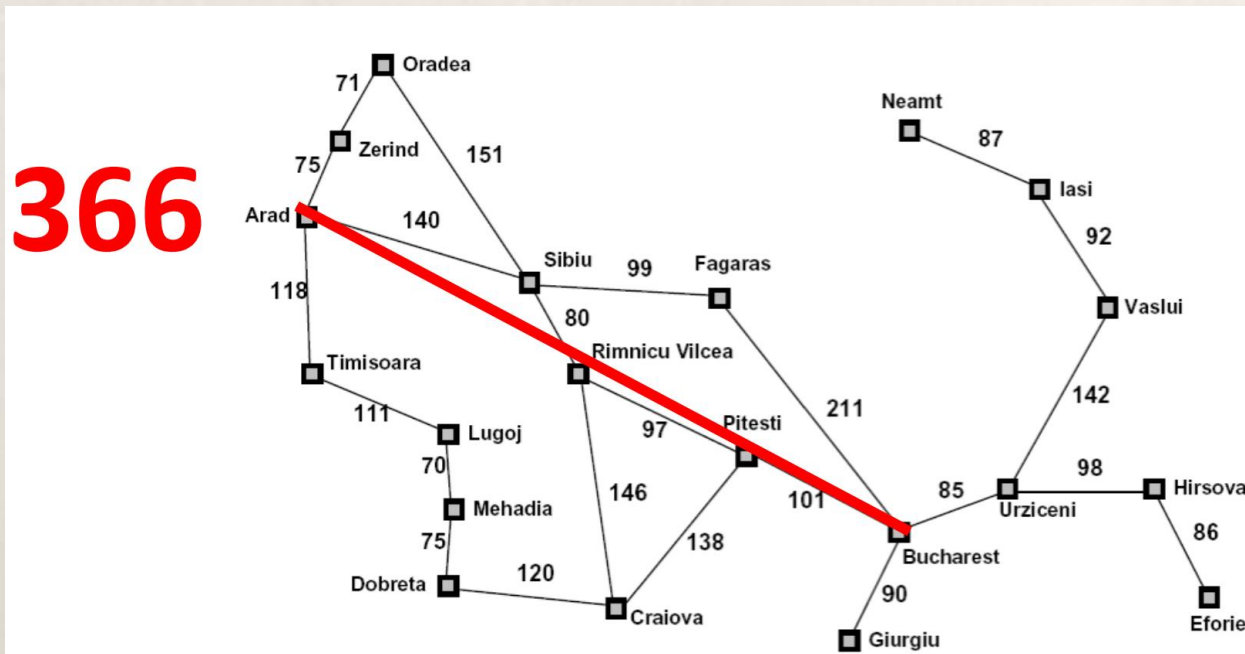

Memory-bounded search: beam search

- A* search with consistent heuristics is **optimally efficient**
- However, if the search problem is hard, it may require too much storage space or computation to complete
- We can sacrifice completeness and optimality of the search algorithm by limiting the size of the frontier
 - A search algorithm is **complete** if it is guaranteed to find a solution in cases where a solution exists
- Limiting the size of the frontier gives us **beam search**
- Assuming the size of the frontier is limited to k nodes, the simplest approach is to keep only the k best nodes
 - An efficient way to do this is to use a min-max heap to implement a double-ended priority queue as the frontier

Creating admissible heuristics

- Most of the work in solving hard search problems optimally is in coming up with admissible heuristics
- Often, admissible heuristics are solutions to relaxed problems, where new actions are available
- Inadmissible heuristics are often useful too

Heuristics for the 8-puzzle

- One admissible heuristic: the number of misplaced tiles
- Better: the sum of the (Manhattan) distances between each tile's current location and its location in the goal state
- These heuristics are both obtained by considering appropriately **relaxed** versions of the original problem
 - Relaxation in the first case: a tile can move anywhere in one move
 - Relaxation in the second case: a tile can move by one square even if that square is already occupied
- Both heuristics are admissible and in fact even consistent (because they provide exact costs for the relaxed problems)
- Another option for getting heuristics is to create a **pattern database** with pre-computed solutions to subproblems
